
NEMS Documentation

Release 0.0.1.beta1

NEMS development team

Apr 04, 2023

GETTING STARTED

1	Generic Python Install	3
2	Conda Installation	5
3	Extra dependencies	7
4	Notes	9
5	Quick Start	11
6	Background and References	13
7	NEMS Demos	15
8	Signals	181
9	Recordings	187
10	Epochs	189
11	Modelspecs	195
12	Modules	201
13	Fitters	203
14	Priors	205
15	XFORMS	207
16	Design Discussions	209
17	History	217
18	NGINX	219
19	nems	221
20	Indices and tables	227

NEMS is the Neural Encoding Model System. It is helpful for fitting a mathematical model to time series data, plotting the model predictions, and comparing the predictive accuracy of multiple models. We use it to develop and test [computational models of how sound is encoded in the brains of behaving mammals](#), but it will work with many different types of timeseries data.

**CHAPTER
ONE**

GENERIC PYTHON INSTALL

If you already have Python and Git, download NEMS:

```
git clone https://github.com/lbhb/NEMS
```

Add the NEMS library via pip (where ./NEMS is the installation directory and -e means editable mode, which is not necessary, but is useful if you end up customizing your model fits):

```
pip install -e ./NEMS
```

NEMS libraries should now be loadable!

**CHAPTER
TWO**

CONDA INSTALLATION

Conda is simple and popular platform for Python package management. NEMS does not currently have a conda package, but you can use conda to manage Python and your other packages. To install NEMS in a conda environment, first download and install Conda from [here](#). Git should be installed with Conda.

Download NEMS:

```
git clone https://github.com/lbhb/NEMS
```

Create a NEMS environment, then activate it and install NEMS:

```
conda env create -n NEMS -f ./NEMS/environment.yml
conda activate NEMS
pip install -e ./NEMS
```

CHAPTER
THREE

EXTRA DEPENDENCIES

NWB: Support for reading datasets stored in Neurodata Without Borders (NWB) format. Pip install the allensdk packages as part of NEMS. You can run this either before or after the generic install described above:

```
pip install -e ./NEMS/[nwb]
```

Tensorflow: If you're using conda to manage packages, it's best to install Tensorflow via conda:

```
# without GPU (run on CPU):  
conda install tensorflow  
# or with GPU support:  
conda install tensorflow-gpu
```

If you're using pip, install Tensorflow support with pip:

```
pip install -e ./NEMS/[tensorflow]
```

Sphinx (if you want to be able to edit and regenerate documentation):

```
pip install -e ./NEMS/[docs]
```

CHAPTER**FOUR**

NOTES

We have found that Python 3 distributions compiled with the Intel MKL libraries are about twice as fast as the default Python implementations that come installed on many linux machines.

NEMS is designed to use Python 3. Backwards compatibility with Python 2 is untested and unsupported.

You may want to add NEMS to your python path. Eg, in Linux:

```
echo "export PYTHONPATH=\\"$PYTHONPATH:`pwd`/NEMS\\"" >> ~/.bashrc
source ~/.bashrc
```

QUICK START

5.1 Start analyzing data

You may test if everything is working by telling NEMS to download some sample auditory stimulus-response data, use a simple linear-nonlinear model (which should take about 2 minutes to fit), and then save the results locally:

```
python demo_script.py
```

Or open `demo_script.py` in an editor to work through each step of the fit.

5.2 I just want to analyze data! Where should I put my script?

If you are just hacking around, please put your code in the `scripts` directory – it's for any one-off analysis or snippet of code that isn't yet ready for reuse by other people. We recommend using `scripts/demo_script.py` as a guide for the types of operations that you may find useful.

There is an `xforms` system for batching and saving analyses in a way that you can reload later; this was what we used in the `scripts/fit_model.py` command. We also have a good tutorial/template at `scripts/demo_script.py`. We recommend beginners make a copy of it and edit it as needed. You can run it with:

```
python scripts/demo_script.py
```

5.3 Where should I put my data? Where should I save my results?

5.3.1 Input Data

If your data is in `Recording` format, put it in the `recordings` directory. If it is not yet in recording form, you may want to make a conversion script in `scripts` that is able to convert your data from your custom format into `Signals` and `Recordings`.

Below is some pseudocode for a script that converts your data from a custom format and then saves it as a `Signal` to make it easier for other people to use.

```
from nems0.signal import Signal

numpy_array = load_my_custom_data_format(...)
sig = Signal(data=numpy_array,
              name='mysignal',
```

(continues on next page)

(continued from previous page)

```
recording='some-string',
fs=200 # Hz
)
sig.save('recordings/my-new-recording/my-new-signal')
```

5.3.2 Output Results

Once you have fit a model to a recording, you can save the resulting files either locally in your `NEMS/results` directory, or to a remote database server.

**CHAPTER
SIX**

BACKGROUND AND REFERENCES

6.1 The Big Picture

6.2 Suggested Reading

This older review paper provides background on the general approach of using encoding models to study sensory processing: https://hearingbrain.org/pdf/wu_david_gallant_annrev_2006.pdf

Here's a more recent study comparing performance of encoding models for auditory cortex that uses the NEMS library: <https://www.biorxiv.org/content/10.1101/534537v3>

And finally, here's a review of behavior state-dependent models of the sort that can be fit using NEMS: <https://www.sciencedirect.com/science/article/pii/S0378595517303611?via%3Dihub>

NEMS DEMOS

7.1 Demo scripts

The NEMS/scripts/ folder contains a number of files demo_*.py that illustrate different aspects of working with NEMS. A good place to start is demo_script.py.

7.2 Demo Notebooks

These demos are formatted as Jupyter notebooks. There are two ways to run them. One is to launch your preferred Python environment with NEMS installed. Then cut/paste code from the pages below into your Python console.

An alternative is to copy the notebooks from nems/docs/source/demos/ to a working directory and open them using Jupyter Notebooks/Jupyter Lab. More information on using Jupyter here: <https://jupyter.org/>

7.2.1 Intro to NEMS

This notebook covers some basic overview of how NEMS works, from loading data to creating a modelspec of a model and evaluating it.

```
[1]: import pickle
from pathlib import Path

import nems0.analysis.api
import nems0.initializers
import nems0.recording as recording
import nems0.uri
from nems0.fitters.api import scipy_minimize
from nems0.signal import RasterizedSignal

[nems.configs.defaults INFO] Saving log messages to /tmp/nems\NEMS 2020-05-28 133134.log
```

Configuration

Raw data is usually saved in the `recording` directory in NEMS. You can specify a custom save data location in your NEMS config file.

```
[2]: # get the data and results paths
signals_dir = Path(nems.NEMS_PATH) / 'recordings'
```

```
[3]: # download some demo data
recording.get_demo_recordings(signals_dir)
datafile = signals_dir / 'TAR010c-18-1.pkl'
```

Load and Format Recording Data

```
[4]: with open(datafile, 'rb') as f:
    cellid, rec_name, fs, X, Y, epochs = pickle.load(f)
```

A recording object contains a set of signal objects, along with some associated metadata. signal objects can be of various types depending on your use case. signal data is stored as channel x time arrays.

```
[5]: # create NEMS formatted signal objects from the raw data
resp = RasterizedSignal(fs, Y, 'resp', rec_name, epochs=epochs, chans=[cellid])
stim = RasterizedSignal(fs, X, 'stim', rec_name, epochs=epochs)
```

```
[6]: # create the recording object from the signals
signals = {'resp': resp, 'stim': stim}
rec = recording.Recording(signals)
```

To validate the model after training, the data is split into `est` and `val` datasets.

```
[7]: est, val = rec.split_using_epoch_occurrence_counts(epoch_regex="^STIM_")
```

Initialize the ModelSpec

ModelSpec names are shorthand keyword strings. The below one defines a model, which constrains the spectral tuning to be gaussian and adds a static output non linearity.

```
[8]: modelspec_name = 'wc.18x2.g-fir.2x15-lvl.1-dexp.1'
```

```
[9]: # record some meta data for display and saving
meta = {'cellid': cellid,
        'batch': 271,
        'modelname': modelspec_name,
        'recording': cellid
       }

modelspec = nems.initializers.from_keywords(modelspec_name, meta=meta)

[nems.initializers INFO] kw: wc.18x2.g
[nems.initializers INFO] kw: fir.2x15
[nems.initializers INFO] kw: lvl.1
```

(continues on next page)

(continued from previous page)

```
[nems.initializers INFO] kw: dexp.1
[nems.initializers INFO] Setting modelspec[0] input to stim
```

Run an Analysis

The model is fit to the data using a basic gradient approach.

```
[10]: modelspec = nems.analysis.api.fit_basic(est, modelspec, fitter=scipy_minimize)

bin range: 0-500

[nems.modelspec INFO] plotting row 6/6
[nems.modelspec INFO] Quickplot: generated fig with title "Cell: TAR010c-18-1, Batch: 271, None #0 wc.18x2.g-fir.2x15-lvl.1-dexp.1"
```

7.2.2 xforms Demo

This notebook demonstrates the use of xforms for generating models that are easy to reload.

```
[1]: import logging
from pathlib import Path

import nems0.db as db
import nems0.modelspec as ms
import nems0.recording as recording
import nems0.uri
import nems0.xforms as xforms

[nems.configs.defaults INFO] Saving log messages to /tmp/nems\NEMS 2020-05-28 141002.log
```

Configuration

```
[2]: # get the data and results paths
results_dir = nems.get_setting('NEMS_RESULTS_DIR')
signals_dir = nems.get_setting('NEMS_RECORDINGS_DIR')
```

```
[3]: # download some demo data
recording.get_demo_recordings(signals_dir)
datafile = Path(signals_dir) / 'TAR010c-18-1.pkl'
```

Data Loading and Preprocessing

```
[4]: load_command = 'nems.demo.loaders.demo_loader'
expt_id = 'TAR010c'
batch = 271
cell_id = 'TAR010c-18-1'
```

```
[5]: modelspec_name = 'dlog-wc.18x1.g-fir.1x15-lvl.1-dexp.1'
```

Generate the Modelspec

Each item in the xform spec is a call to a function along with the arguments for that function.

```
[6]: xfspec = []
```

```
[7]: # load from external format
xfspec.append(['nems.xforms.load_recording_wrapper',
    {'load_command': load_command,
     'exptid': expt_id,
     'datafile': str(datafile)
    }])
```

```
[8]: # split the data into est and val
xfspec.append(['nems.xforms.split_by_occurrence_counts',
               {'epoch_regex': '^STIM_'}])

[9]: xfspec.append(['nems.xforms.average_away_stim_occurrences', {}])

[10]: meta = {'cellid': cell_id, 'batch': batch, 'modelname': modelspec_name, 'recording':  
        ↪expt_id}

xfspec.append(['nems.xforms.init_from_keywords',
               {'keywordstring': modelspec_name,
                'meta': meta
               }])

[11]: # init, then fit
xfspec.append(['nems.xforms.fit_basic_init', {}])
xfspec.append(['nems.xforms.fit_basic', {'tolerance': 1e-6}])

[12]: xfspec.append(['nems.xforms.predict', {}])

[13]: # test prediction then visualize
xfspec.append(['nems.analysis.api.standard_correlation', {},
               ['est', 'val', 'modelspec', 'rec'], ['modelspec']])
xfspec.append(['nems.xforms.plot_summary', {}])
```

Run the Analysis

```
[14]: ctx = []
for xfa in xfspec:
    ctx = xforms.evaluate_step(xfa, ctx)

```
[15]: # get a unique dir to save the modelspec to
destination = Path(results_dir) / str(batch) / xforms.get_meta(ctx)['cellid'] / ms.get_
↪modelspec_longname(ctx['modelspec'])
destination = str(destination)
```

```
[16]: xforms.save_analysis(destination,
                           recording=ctx['rec'],
                           modelspec=ctx['modelspec'],
                           xfspec=xfspec,
                           figures=ctx['figures'],
                           log='NO LOG')
```

```
[16]: {'savepath': 'C:\\\\Users\\\\Alex\\\\PycharmProjects\\\\NEMS\\\\results\\\\271\\\\TAR010c-18-1\\\\
↪TAR010c.dlog_wc.18x1.g_fir.1x15_lvl.1_dexp.1.fit_basic.2020-05-28T211146/'}
```

```
[ ]: # save summary of results to a database
modelspec = ctx['modelspec']
modelspec.meta['modelpath'] = destination
modelspec.meta['figurefile'] = destination + 'figure.0000.png'
db.update_results_table(modelspec)
```

7.2.3 Basic xform Usage

The combination of `xforms` and `modelspecs` allows for a compact representation of a workflow, from data loading to model fitting to analysis and more. Below is a simple example of how in a few lines of code, this can be achieved.

```
[1]: from pathlib import Path

import nems0.uri
import nems0.recording as recording
import nems0.xform_helper as xhelp
```

7.2.4 Download Sample Data

Here we quickly download a sample recording to be used in this example. This data is in the form of a `recording` object, which contains a set of `signals` which are containers for each of the data channels (here, the `stim` and `resp` data that we use in the fit).

```
[2]: # save the demo data the default data directory
signals_dir = nems.get_setting('NEMS_RECORDINGS_DIR')
# download the demo data: cell "TAR010c-18-1"
recording.get_demo_recordings(signals_dir, 'TAR010c-18-1.tgz')
datafile = Path(signals_dir) / 'TAR010c-18-1.tgz'
```

7.2.5 Run the Analysis

We specify the name of the analysis we want to run, which consists of a set of keywords for the loader (`ld-sev`), the model (`dlog-wc.18x2.g-fir.2x15-lvl.1-dexp.1`), and the fitter (`basic`), and pass that information to the `xform` function which will build the analysis pipeline and fit the model.

```
[3]: # pass in the relevant information
xfspec, ctx = xhelp.fit_model_xform(
    cellid='TAR010c-18-1',
    batch=289,
    modelname='ld-sev_dlog-wc.18x2.g-fir.2x15-lvl.1-dexp.1_basic',
    returnModel=True,
    saveInDB=False,
    recording_uri=str(datafile),
)

7.2.7 xforms with Tensorflow

This notebook demonstrates the use of xforms for generating models that are easy to reload, using tensorflow as the fitter. The process is very similar to normal workflows, except when specifying the fitter, `fit_tf` rather than `fit_basic` is used.

```
[1]: import logging
from pathlib import Path

import nems0.db as db
import nems0.modelspec as ms
import nems0.recording as recording
import nems0.uri
import nems0.xforms as xforms

[nems.configs.defaults INFO] Saving log messages to /tmp/nems\NEMS 2020-05-28 133629.log
```

Configuration

```
[2]: # get the data and results paths
results_dir = nems.get_setting('NEMS_RESULTS_DIR')
signals_dir = nems.get_setting('NEMS_RECORDINGS_DIR')
```

```
[3]: # download some demo data
recording.get_demo_recordings(signals_dir)
datafile = Path(signals_dir) / 'TAR010c-18-1.pkl'
```

Data Loading and Preprocessing

```
[4]: load_command = 'nems.demo.loaders.demo_loader'
expt_id = 'TAR010c'
batch = 271
cell_id = 'TAR010c-18-1'
```

```
[5]: modelspec_name = 'dlog-wc.18x1.g-fir.1x15-lvl.1-dexp.1'
```

Generate the ModelSpec

Each item in the xform spec is a call to a function along with the arguments for that function.

```
[6]: xfspec = []
```

```
[7]: # load from external format
xfspec.append(['nems.xforms.load_recording_wrapper',
               {'load_command': load_command,
                'exptid': expt_id,
                'datafile': str(datafile)
               }])
```

```
[8]: # split the data into est and val
xfspec.append(['nems.xforms.split_by_occurrence_counts',
               {'epoch_regex': '^STIM_'}])

[9]: xfspec.append(['nems.xforms.average_away_stim_occurrences', {}])

[10]: meta = {'cellid': cell_id, 'batch': batch, 'modelname': modelspec_name, 'recording':  
        ↪expt_id}

xfspec.append(['nems.xforms.init_from_keywords',
               {'keywordstring': modelspec_name,
                'meta': meta
               }])

[11]: # init, then fit
xfspec.append(['nems.tf.cnmlink.fit_tf_init', {}])
xfspec.append(['nems.tf.cnmlink.fit_tf', {}])

[12]: xfspec.append(['nems.xforms.predict', {}])

[13]: # test prediction then visualize
xfspec.append(['nems.analysis.api.standard_correlation', {},
               ['est', 'val', 'modelspec', 'rec'], ['modelspec']])
xfspec.append(['nems.xforms.plot_summary', {}])
```

Run the Analysis

```
[14]: ctx = {}
for xfa in xfspec:
    ctx = xforms.evaluate_step(xfa, ctx)

7.2.8 Population Models

This notebook demonstrates how to work with population models. See `xforms Demo` for details on xforms.

```
[1]: from pathlib import Path

import nems0.uri
import nems0.xforms as xforms
import nems0.recording as recording

[nems.configs.defaults INFO] Saving log messages to /tmp/nems\NEMS 2020-05-29 110208.log
```

Configuration

```
[2]: # get the data and results paths
results_dir = nems.get_setting('NEMS_RESULTS_DIR')
signals_dir = nems.get_setting('NEMS_RECORDINGS_DIR')

[3]: # download some demo data
recording.get_demo_recordings(signals_dir, 'TAR010c.NAT.fs100.tgz')
datafile = Path(signals_dir) / 'TAR010c.NAT.fs100.tgz'
```

Data Loading and Preprocessing

```
[4]: load_command = 'nems.demo.loaders.demo_loader'
exptid = 'TAR010c'
batch = 271
siteid = 'TAR010c'
```

In pop models, you can specify a variable number of outputs using R, and the model will determine the proper number of output channels.

```
[5]: modelspec_name = 'dlog-wc.18x3.g-fir.1x10x3-relu.3-wc.3xR-lvl.R'
```

Generate the ModelSpec

```

7.3 NWB Stuff

7.3.1 Working With NWB Files

[1]:

```

from pathlib import Path
import json

import numpy as np
import pandas as pd

from allensdk.brain_observatory.ecephys.ecephys_project_cache import EcephysProjectCache
from allensdk.brain_observatory.ecephys.ecephys_session import EcephysSession

from allensdk.brain_observatory.ecephys import nwb # for compat
import pynwb
from pynwb import NWBHDF5IO

import nems
from nems0.recording import Recording
from nems0.signal import PointProcess

import h5py

from matplotlib import pyplot as plt

```

[nems.configs.defaults INFO] Saving log messages to /tmp/nems/NEMS 2019-12-10 155251.log

Generate session and get metadata

```
[2]: data_dir = Path(r'data')
manifest_path = data_dir / 'manifest.json'
```

`manifest.json` is where the library keeps a record of previously downloaded files. If it doesn't exists in location you specify, it will be created the first time you create the cache object. Otherwise, when you request data, the library will check the manifest to see if it's been downloaded.

```
[3]: # assert manifest_path.exists()
```

```
[4]: cache = EcephysProjectCache.from_warehouse(manifest=manifest_path)
sessions = cache.get_session_table()
```

```
[call_caching INFO] Reading data from cache
[numexpr.utils INFO] NumExpr defaulting to 8 threads.
[call_caching INFO] Reading data from cache
```

Download data from session

You can edit the download criteria to filter out the data. Downloading the data can take several minutes.

```
[5]: # 21 is just a random number, for this example notebook
session = cache.get_session_data(sessions.iloc[21].name,
                                  isi_violations_maximum=np.inf,
                                  amplitude_cutoff_maximum=np.inf,

```

Loading existing NWB files with session

If you've previously downloaded data, you can avoid the cache creation and just create a session from an NWB file.

```
[9]: nwb_filepath = Path(r'/auto/users/tomlinsa/code/allen/data/session_760345702/session_
→760345702.nwb')
assert nwb_filepath.exists()

[10]: session = EcephysSession.from_nwb_path(str(nwb_filepath), api_kwargs={
        "amplitude_cutoff_maximum": np.inf,
        "presence_ratio_minimum": -np.inf,
        "isi_violations_maximum": np.inf
    })
```

```
[11]: # session.stimulus_presentations
```

or from NWB file (preferred)

This is the raw data. The session method of getting the data does it's own formatting of the dataframes.

```
[12]: nwb_filepath = Path(r'/auto/users/tomlinsa/code/allen/data/session_760345702/session_760345702.nwb')
       assert nwb_filepath.exists()
```

```
[13]: io = NWBHDF5IO(str(nwb_filepath), 'r')
       nwbfile = io.read()
```

```
[14]: nwbfile.lab_meta_data
```

```

Get stimulus images

For example, frame 100 from natural_scenes, as in this random row:

```
[23]: r.epochs.loc[[51357], ['start', 'end', 'name', 'frame']] # list loc to keep as df
[23]:      start        end         name   frame
51357  5910.169789  5910.420001  natural_scenes  100.0
```

```
[24]: im = cache.get_natural_scene_template(100)
[call_caching INFO] Reading data from cache
```

```
[25]: plt.imshow(im, cmap=plt.cm.gray)
[25]: <matplotlib.image.AxesImage at 0x7fd3ea60bf60>
```

SIGNALS

Signals are the fundamental NEMS objects for storing timeseries data. They represent a value that changes in time, like the volume level of a speaker, the voltage across the membrane of a neuron, or the coordinates of a moving insect.

Signals are objects designed to be useful for signal processing operations, slicing, averaging, jackknifing, truncating, splitting, saving/loading, dividing data into estimation and validation subsets, selecting parts of data where a condition is true, concatenating data sets together, and other common data wrangling tasks.

You can create Signal objects *from a file*, *from another signal*, or *from a matrix*.

An important note for beginners: once created, a Signal object cannot be changed – it is **immutable**, just like tuples in Python. This is intentional and enables specific optimizations while also preventing entire classes of errors. But don't worry: we have made it easy to create new Signal objects based on other ones.

8.1 What is a signal?

Fundamentally, a Signal represents C channels being sampled for some period of time. Because NEMS is designed for signal processing, we usually assume that the sampling occurs T times at regular intervals, in which case the signal is “rasterized” at a particular sampling rate, and we represent the signal as an C x T array.

You may request this array using the `.as_continuous()` method of any signal.

A Signal can represent any type of data, such as subject pupil diameter, local field potential (LFP), or a measurement of average neural spike rate during each discrete sampling period.

8.2 Working with signals

Signal objects support basic and label-based indexing, which returns a new Signal object. Basic indexing is accessed using the special `Signal.iloc[channel_slice, time_slice]` syntax. You must use integers. For example, to select the first 5 channels and the second set of 25 timepoints:

```
trimmed = signal.iloc[:5, 25:50]
```

In contrast, label-based indexing allows you to select by channel name and/or time. To select the named channels up to (and including) ‘chan5’ and the timepoints from 1.5 to 2 seconds:

```
# Get all channels up to, and including chan5, include only timepoints from 1.5 to 2
seconds.
trimmed = signal.loc[:, 'chan5', 1.5:2]
```

(continues on next page)

(continued from previous page)

```
# Get only chan5. Include all timepoints.  
trimmed = signal.loc['chan5']
```

Note that the named-channel slice endpoint *includes* the label. This is in contrast to Python index conventions where endpoints are usually exclusive. The endpoints are exclusive for the basic indexing and time portion of the slice.

8.3 Loading Signals from files

The majority of the time, you will be loading a `Signal` stored on disk. At a minimum, you will need a CSV file (which holds the tabular data, like a 2D matrix) and a JSON file, which stores metadata and documents what kind of data is in the CSV file.

Optionally, you will also often have an “epochs” file, which helps tag interesting events or periods of time in the timeseries for later analysis, but we will defer *the detailed documentation of epochs* until later.

Loading a `Signal` from a file is trivial:

```
from nems0.signal import Signal  
signal = Signal.load('path/to/my/signalfies')
```

Creating your own CSV files is pretty straightforward, but you need to understand the format. Read on if that interests you, or *jump ahead if you would rather make Signal objects from a numpy array*.

8.3.1 Example Signal CSV File

For this example, make a new directory in the `signals` directory called `testrec` because we are pretending we made a test recording, and usually we group a collection of signals together into a data structure called a `Recording`.

Inside the `testrec` directory, make a file called `testrec_pupil.csv` and put the following CSV data inside it:

```
2.0, 2.1  
2.5, 2.5  
2.3, 2.3  
2.4, 2.5  
2.4, 2.3  
2.3, 2.4
```

In the CSV file, each row represents an instant in time, and each column is a “channel” of information of this signal. Channels can be anything you want – they are just there to help you group several dimensions together.

For this example, we’ll pretend the first channel is the diameter of a test subject’s left pupil and the second channel is their right eye. There are only two channels and six time samples here, but in many experiments you will have tens of channels and thousands or millions of time samples.

8.3.2 Example Signal JSON File

Continuing our example, let's make a JSON file that describes the contents of the CSV file containing our pupil data.

In the `signals/testrec` directory, make another file called `testrec_pupil.json` and fill it with:

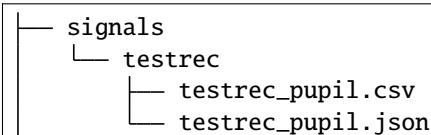

```
{
    "recording": "testrec",
    "name": "pupil",
    "chans": [
        "left_eye",
        "right_eye"
    ],
    "fs": 0.1,
    "meta": {
        "Subject": "Don Quixote",
        "Age": 36
    }
}
```

Here,

- `recording` is the name of the recording. We group collections of signals into “recordings”, which is just a name to help us group simultaneously recorded signals.
- `name` is the name by which you want to refer to this signal. Generally it should match your file name so as not to be confusing.
- `fs` is the sampling rate in Hz. Generally it will be 10, 50, or even 44,200Hz, but for our test example, we assume that a measurement of the pupil diameter was only taken every 10 seconds, so `fs=0.1`.
- `chans` is the name of each channel (i.e. column in the CSV file), from left to right.
- `meta` is extra information about the recording, such as the time of day it was taken, the experimenter, the subject, their age, or other relevant information. You may place anything you want here as long as it is a valid JSON data structure.

8.3.3 Loading Example CSV + JSON

Assuming that your signal directory looks like this:

You should now be able to load the pupil signal by creating a file at `scripts/pupil_analysis.py` with the contents:

```
from nems0.signal import Signal

# Note that we don't append the suffix .json or .csv
# because we are loading two files simultaneously
signal = Signal.load('signals/testrec/testrec_pupil')
```

And launch it from your terminal with:

```
cd /path/to/nems
python scripts/pupil_analysis.py
```

That's it! You can start using your Signal now. Read on to find a short guide to interesting operations that you can do with a Signal.

8.4 Creating Signals from Other Signals

It's really common to make one signal from another signal. At the moment, we have a variety of methods that are rather in development flux, but the ones that produce new signals include:

```
normalized_by_mean(self)
normalized_by_bounds(self)
split_at_time(self, fraction)
jackknifed_by_epochs(self, epoch_name, nsplits, split_idx, invert=False)
jackknifed_by_time(self, nsplits, split_idx, invert=False)
concatenate_time(cls, signals)
concatenate_channels(cls, signals)
```

TODO: Link to python-generated documentation here.

8.5 Creating Signals from Numpy Arrays

This technique for creating signals is most common when importing or loading data from a custom format. In general, we encourage you to avoid saving your data in custom formats so that data files are more easily shared, but if you have special needs, then writing your own custom signal loader or subclass of `Signal` is completely acceptable.

```
from nems0.signal import Signal

numpy_array = load_my_custom_data_format(...)

# Not shown here, but we suggest using optional arguments "epochs" and "meta"
# as well as recording, name, matrix, and fs.
signal = Signal(recording='my_recording_name',
                 name='my_signal_name',
                 matrix=numpy_array,
                 fs=200)

# Optional: save it as a signal for next time or for easy sharing
signal.save('../signals/my-new-signal')
```

8.6 Signal Subclasses

We will now discuss two subclasses of signals that can be useful to reduce data storage on disk, but are otherwise functionally identical.

8.6.1 Subclass: EventSignals

Now, the signal processing view of a `Signal` is “external” view that we actually use during signal processing. However, as the sampling rate gets faster and faster, the $C \times T$ representation of a `Signal` becomes more and more wasteful. For events that occur only occasionally, we can save space if we store a list of discrete event times, rather than having a matrix of mostly zeros with only a few ones.

In this case, we use a subclass of the `Signal` object called an `EventsSignal`, which may be rastered into time bins at any sampling frequency desired, and then used as a normal `Signal` from there on.

8.6.2 Subclass: RepeatedSignal

A second special case occurs, for example, when we have stimuli that are repeated tens or hundreds of times. While such a stimulus can certainly be represented with a $C \times T$ array, it is again a wasteful representation.

In such cases, the `RepeatedSignal` subclass of the `Signal` object is useful. Rather than store a large raster, it stores a single copy of each unique event and rasterizes it only as requested.

For example, say we have a P-channel spectrogram and several different stimuli of different lengths S_1, S_2 , etc. The `RepetitiveSignal` internally stores a `{name1: [C x S_1], name2: [C x S_2], ...}` dictionary, in which the keys are the names/labels of the stimuli and the $[C \times S_*]$ arrays are what to insert.

The `RepetitiveSignal` object thus rasterizes signals on demand by using a signal’s `.epochs` datastructure and the `.replace_epochs()` method to produce a $C \times T$ matrix only when needed.

8.7 Closing Thoughts on Signals

If you want to have a model that uses the data from 100 neurons, you can either have a single 100-channel `Signal`, or 100 one-channel signals. It’s up to you.

8.7.1 Signals Implement the Numpy Interface

`Signals` implement the Numpy universal function interface. This means that you can perform a variety of array operations on `Signals`:

```
# Add a DC offset of 5 to the signal
offset_signal = signal + 5

# Matrix multiplication
weighted_channels = weights @ signal

# Multi-signal operations (stim and pupil are signals)
pred = stim * pupil + stim * pupil**2 + stim * pupil**3

# Apply a linear filter to the signal. A new signal is created as fir
```

(continues on next page)

(continued from previous page)

```
fir = lfilter(b, a, stim)

# Now, average across the filtered channels.
fir_mean = fir.mean(axis=0)
```

When performing an operation on a signal, a new signal object is returned. The signal will be identical to the original object, albeit with appropriately-transformed data (e.g., sampling rate and epochs will be copied over).

If you attempt to perform an operation (e.g., adding two signals) that do not match in some attribute (e.g., number of samples, sampling rate, etc.) you'll get an error.

RECORDINGS

9.1 What is a recording?

A Recording is collection of *signals* sampled simultaneously over the same time period. The key point is that all the signals' time indexes line up, which implies that they were sampled at the same rate and have their arrays have the same length in the time dimension.

Recordings provide a way for you to group related data, for example when simultaneously recording neural activity (a signal with several channels, one per neuron), the ambient sound heard (another signal), and the test subject motion (yet another signal, whose channels describe XYZ coordinates). Because all three signals occurred at the same time and may need to be considered together during analysis, they should be part of the same Recording.

9.2 How are Recordings saved?

When saved as files, Recordings are represented as directories containing Signals, which are represented as 2-3 files. For example, a hierarchy might look like:

```
└── gus027b13_p_PPS
    ├── gus027b13_p_PPS.pupil.csv
    ├── gus027b13_p_PPS.pupil.json
    ├── gus027b13_p_PPS.resp.csv
    ├── gus027b13_p_PPS.resp.epochs.csv
    ├── gus027b13_p_PPS.resp.json
    ├── gus027b13_p_PPS.stim.csv
    ├── gus027b13_p_PPS.stim.epochs.csv
    └── gus027b13_p_PPS.stim.json
```

As you can see,

1. There is one directory holding all the signals in the recording (`gus027b13_p_PPS` is the name of the recording);
2. Each signal (`pupil`, `resp`, and `stim` in this case) is represented by two tabular CSV files and one JSON file. Files that end in '`.epochs.csv`' contain information that tag individual events and regions of time. Note that there are no tagged epochs for the `pupil` signal, while the `stim` signal presumably has information tagging when specific sounds were played, and the `resp` signal presumably has information about how the animal behaved or responded.

More details on signal file formats may be found on the Signals documentation page.

10.1 What is an Epoch?

An epoch is an event or period of time that has been tagged with a name. Epochs are attached to Signal objects. A recording, which contains a collection of signals, has methods that allow us to manipulate the entire collection based on a superset of the epochs in each signal.

An epoch has three values:

start, end, name

where `start` and `end` denote the beginning and end of the epoch in seconds and `name` is a descriptive string (see [how to name epochs](#). For events (single points in time), the `start` will contain the timestamp of the event and `end` will be NaN. Currently, support for events are limited (or nonexistent). As use-cases arise, we will implement support for these.

Epochs are stored in [Signal objects](#) under the `.epochs` attribute in a pandas DataFrame containing three columns (`start`, `end` and `name`).

For the rest of this document, let's consider some example epoch data in which trials are 40-100 msec long, and there are several TORCs of 20 msec duration played before a tone-in-TORC detection task. In this task, the subject is asked to detect when a tone is played in a sequence of background tokens (known as TORCs).

start	end	name
0.00	0.060	ExperimentalTrial
0.00	0.05	PreStimSilence
0.00	0.020	TORC_3983
0.00	0.020	Reference
0.015	0.020	PostStimSilence
0.020	0.025	PreStimSilence
0.020	0.040	TORC_572
0.020	0.040	Reference
0.035	0.040	PostStimSilence
0.040	0.045	PreStimSilence
0.040	0.060	TORC_3983
0.040	0.060	PureTone12
0.040	0.060	DetectionTask
0.049	0.049	Licking
0.055	0.060	PostStimSilence
0.060	0.0100	ExperimentalTrial
0.060	0.065	PreStimSilence

(continues on next page)

(continued from previous page)

0.060	0.080	TORC_444
0.060	0.080	Reference
0.066	0.087	Licking
0.075	0.080	PostStimSilence
0.080	0.0100	TimeOut

In the example above, note that some epochs have the same name, such as “ExperimentalTrial”. If the same name appears several times, we call each appearance an *occurrence* of a given epoch.

Note also that epochs may overlap. For example, compare the first TORC_3983 with the first Reference. This is a way of indicating that TORC_3983 is a Reference token. This approach facilitates analysis where one may wish to select all reference TORCs and compare them to all TORCs that occur simultaneously with a pure tone (compare the second occurrence of TORC_3983 with PureTone12).

This set of epochs tells us quite a bit about what’s going on in the experiment. In the first trial two reference TORCs are played (TORC_3983, TORC_572), then a tone-in-TORC is played (TORC_3983, PureTone12), and the animal correctly licks. In the second trial, the animal licks during the reference sound and gets a time out.

10.2 How signals use epochs

A signal object can use epochs to perform two basic operations:

- Mask regions of data. For example, perhaps licking introduces EMG artifacts into the LFP recordings. In this case, you may want to mask all regions in the LFP recording during a lick so that your analysis isn’t affected by these artifacts:

```
masked_signal = signal.mask\epoch('Licking')
```

As you will see later, this masking can also be used to generate subsets of data for cross-validation when fitting models. Signals also have a `select_epochs` method, which is the inverse of `mask_epochs`:

```
selected_signal = signal.select_epoch('Reference')
```

- Extract regions of data. For example, perhaps you want to plot the average response to a particular epoch:

```
torc = signal.extract_epoch('TORC\_3983')
average_torc = np.nanmean(torc, axis=0)
```

10.3 Epoch manipulation

Signal objects offer the following methods:

- Getting boundaries of an epoch stored inside the signal using `signal.get_epoch_bounds(epoch_name)`. This will return a Nx2 array (where N is the number of occurrences, the first column is start time and the second column is end time).
- Adding epochs to the ones stored inside the signal. You can do this using `signal.add_epoch(epoch_name, epochs)`.

Fancy manipulation of epochs (e.g., selecting epochs that contain another epoch, resizing epoch boundaries, computing the union of two epochs, etc.) must be done outside the signal object. You can then add the newly-created epochs back to the signal object.

10.3.1 General epoch manipulation

Internally, signal objects store epochs in a DataFrame with three columns ('start', 'end', 'name'). However, when working with epochs outside of the signal object, the epochs will be a 2D array of shape Nx2 (where N is the number of occurrences of that epoch, the first column is start time and second column is end time). In the example below, we have four occurrences of the epoch, with the last epoch running from 300 to 301 msec:

```
[[0.049  0.049],
 [0.066  0.087],
 [0.145  0.257],
 [0.300  0.301]]
```

To pull some epochs out for processing, you can use `signal.get_epoch_bounds`:

```
dt_epoch = signal.get_epoch_bounds('DetectionTask')
l_epoch = signal.get_epoch_bounds('Licking')
```

If we want to take only the correct trials (defined as when the animal licks during a detection task):

```
from nems0.data.epochs import epoch_contain
correct_epoch = epoch_contain(dt_epoch, l_epoch, mode='start')
```

Then, mask everything but the correct epochs:

```
masked_signal = signal.select_epoch(correct_epochs)
```

Great! You can save that for later by adding it to the epochs in the Signal:

```
signal.add_epoch('CorrectTrial', correct_epochs)
```

Then anytime afterward we can simply do:

```
correct_signal = signal.select_epoch('CorrectTrial')
```

10.3.2 Manipulating epoch boundaries

You can use set theory to manipulate epoch boundaries by subtracting or adding one epoch to the other:

```
from nems0.data.epochs import epoch_intersection, epoch_difference

ct_epoch = signal.get_epoch_bounds('CorrectTrial')
prestim_epoch = signal.get_epoch_bounds('PreStimSilence')

# Get only the prestim silence by combining using an intersection operation
only_prestim = epoch_intersection(ct_epoch, prestim_epoch)

# Remove the prestim silence by using a difference operation
no_prestim = epoch_difference(ct_epoch, prestim_epoch)
```

10.3.3 How do I get the average response to a particular epoch?

Instead of masking data with `signal.select_epoch()` and `signal.mask_epoch()`, you may also extract epochs:

```
data = signal.extract_epoch('TORC_3983')
average_response = np.nanmean(data, axis=0)
```

Here, `extract_epoch` returns a 3D array with the first axis containing each occurrence of TORC_3983. The remaining two axes are channels and time. In this particular situation, the durations of each occurrence of TORC_3983 are identical. However, in some situations, the duration of epochs may vary from occurrence to occurrence. In this case, shorter epochs will be padded with NaN values so the length matches the longest occurrence. To get the average, use `np.nanmean`.

10.3.4 How do I get the average response in prestim vs poststim, regardless of behavior?

This might be useful for identifying a baseline that is altered by behavior.

```
signal.select_epochs('PreStimSilence', inplace=True)
prestim = signal.as_continuous()
prestim_mean = np.nanmean(prestim)

signal.select_epochs('PostStimSilence', inplace=True)
poststim = signal.as_continuous()
poststim_mean = np.nanmean(poststim)
```

10.3.5 How do I get the average stimulus 300ms before every mistaken lick?

What if we want to know what the animal heard just before it licked accidentally? Or if the TORC was maybe too close to the reference tone?

```
# Pull out the epoch we want to analyze
trial_epoch = signal.get_epoch_bounds('Trials')
ct_epoch = signal.get_epoch_bounds('CorrectTrials')

# Note the invert=True. This means to return all trial_epoch that do not
# contain a ct_epoch.
bad_trials = epoch_contain(trial_epoch, ct_epoch, invert=True)

# Extend the 'licking' events backward 300ms
lick_epoch = signal.get_epoch_bounds('Licking')
prior_to_licking = adjust_epoch(lick_epoch, -300, 0)

# Now take the intersection of those two selections
before_bad_licks = epoch_intersection(bad_trials, prior_to_licking)

signal.select_epoch(before_bad_licks, inplace=True)
data = signal.as_continuous()
some_plot_function(data)
```

Note that `extract_epoch` may end up duplicating data. For example, if the animal licked 10 times a second and you were looking at the 3 seconds prior to each lick, your data will overlap, meaning you just duplicated your total data about

$1/2 * 3 * 10 = 15$ times! This may negatively alter certain computations of the mean in some sense, and in such circumstances, you may want to use the argument `allow_data_duplication=False` for `signal.extract_epoch()`.

10.3.6 How do I use epoch info from two different signals in the same recording?

Like signal objects, recording objects offer `mask_epoch` and `extract_epoch` methods. However, you still need to combine the epochs manually. In the above examples, we assumed that a single signal will contain information about both the stimulus and whether the animal licked or not. However, that may not always be the case. Perhaps the “stimulus” signal will contain information about the stimulus and trials while the “lick” signal will contain information about the lick epochs (i.e., how the animal responded). For example, if we want to find any time the animal blinked or licked and treat those as artifacts and mask the full recording when they occurred).

```
# The recording version of `get_epoch_bounds` takes the signal name as the
# first argument and epoch name as the second argument.
lick_epoch = recording.get_epoch_bounds('lick', 'Licking')
blink_epoch = recording.get_epoch_bounds('pupil', 'blinks')

all_artifacts = epochs_union(blink_epoch, lick_epoch)
recording.mask_signals(all_artifacts)
```

10.4 Epoch naming

Be descriptive. If you give a stimulus a unique name, then when it occurs in other Recordings, you can simply concatenate the two recordings and still select exactly the same data.

Avoid implicit indexes like `trial1`, `trial2`, `trial3`; prefer using just `trial` and the folding functionality of `.fold_by('trial')`, which gives you a matrix. If you have truly different stimuli, you may name them `stim01`, `stim02`, but descriptive names like `cookoo_bird.wav`, and `train_horn.wav` are better.

Remember that the idea behind epochs is to tag the content of data, much like HTML marks up text to tell what it is. It's totally fine to tag the exact same epoch with multiple names, if that will help you perform queries on it later.

10.5 What happens with zero-length epochs?

Zero-length epochs are events. They work best with `epochs_contain`:

```
trials = signal.get_epochs('Trial')

# Assume a laser is an event (i.e., a zero-length epoch)
laser_pulse = signal.get_epochs('Laser')

laser_trials = epochs_contain(trials, laser_pulse, mode='start')
```

They will not work with set operations.

10.6 Cross-validation and Jackknives

```
from nems0.data.epochs import jackknife_epochs
stim = recording.get_signal('stim')
trials = stim.get_epochs('trials')

# Generate 20 jackknife sets
jacknifed_trials = jackknife_epochs(n=20)

results = []
for jackknife in jacknifed_trials:
    est = recording.mask_epochs(jackknife)
    val = recording.select_epochs(jackknife)
    result = fit_model(est, val, model)
    results.append(result)

plot_result(result)
publish_paper(result)
```

MODELSPECS

11.1 What's a ModelSpec?

A modelspec is a data structure that unambiguously defines a sequence of transformations in a NEMS model. It is a simple, minimalist format that is easily saved and loaded to disk.

A modelspec is essentially an ordered list of dicts. Each dict describes a single *module* that performs an input-output transformation performed by a pure function (*fn*). An example of a simple modelspec before fitting is:

```
[{"id": "wc18x1",
 "fn": "nems.modules.weight_channels.weight_channels",
 "fn_kwargs": {"input": "stim-spectrogram",
               "output": "pred"},  

 "prior": [TODO]},  

 {"id": "fir10x1",
 "fn": "nems.modules.fir.fir_filter",
 "fn_kwargs": {"input": "pred",
               "output": "pred"},  

 "prior": [TODO]},  

 {"id": "dexpl",
 "fn": "nems.modules.nonlinearity.double_exponential",
 "fn_kwargs": {"input": "pred",
               "output": "pred"},  

 "prior": [TODO]}]
```

After fitting, that same modelspec might look like this:

```
[{"id": "wc18x1",
 "fn": "nems.modules.weight_channels.weight_channels",
 "fn_kwargs": {"input": "stim-wav",
               "output": "pred"},  

 "phi": {"coefficients": [[0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1,
                            ↪ 0.1, 0.1, 0.1, 0.1, 0.1, 0.1]]},  

 "prior": [TODO],  

 "meta": {"initializers": ["prefitwc3"],  

          "fit_start": "2018-02-02T20:33Z",  

          "fit_end": "2018-02-02T29:14Z",  

          "datasets": ["por39c-39", "gus038a-a2"],  

          "fitters_used": ["iterfit39", "adagrad2"]}},  

 {"id": "fir10x1",
 "fn": "nems.modules.fir.fir_filter",
```

(continues on next page)

(continued from previous page)

```
"fn_kwargs": {"input": "pred",
              "output": "pred"},  

"phi": {"coefficients": [[0, 1.0, 0, 0, 0, 0, 0, 0, 0, 0]],  

        "prior": [TODO]},  

{"id": "dexp1"  

 "fn": "nems.modules.nonlinearity.double_exponential",  

 "fn_kwargs": {"input": "pred",
               "output": "pred"},  

"phi": {"amplitude": 1.0,  

        "shift": 1.0,  

        "base": 1.0,  

        "kappa": 1.0},  

"prior": [TODO]}]
```

More on the *modules* that comprise modelspecs here.

11.2 What's an Initializer? What are module keywords?

Often, we will be reusing the same module dicts over and over again, with the only thing that changes being the parameter values `phi` which resulted from fitting the model to some specific data. Rather than write out the modelspec from scratch every single time, we can use an `initializer` function to create a modelspec for us.

If you know the shape of the data coming in, you may directly create a modelspec using short abbreviations called “keywords”. For example, we could have created the above modelspec using:

```
my_modelspec = initializers.from_keywords('wc18x1_fir10x1_dexp1')
```

The `from_keywords` initializer accepts an underscore separated string to make a list of keywords, and then each keyword is replaced with a dict that was looked up in `nems.keywords.defaults`. (You may use your own dictionary if you wish however, using the `registry={...}` argument.)

This is a very simple initializer to be sure, but it has several advantages:

- 1) Every time we see `fir10x1`, we know that it maps to a modelspec with a FIR filter that has a known shape – in this case, 10 time bins by 1 channel. This makes studying parameters simpler than if we used `fir10` and did not know the number of input channels. In such a case, to find the matrices that we want, we would need to look at all of the `fir10` objects, determine the shape of the coefficients matrix, and then discard those that don't match what we wanted. Conversely, we immediately know that `fir10x1` is not the same as `fir10x2` because they have different numbers of channels and the keywords are not identical.
- 2) If `fir10x1` is *saved in the modelspec filename*, you can easily find all filenames containing this keyword, and easily extract/merge their contents to determine the distribution of post-fit parameter values.
- 3) Sometimes the same function is used in multiple ways, and module keywords can help provide metadata about the way in which it was intended to be used. For example, we may use two FIR filters in a single model, one of which uses the “active” part of behavioral data and the other which makes predictions on the “passive” behavioral data. By using two keywords, `fir10x1active` and `fir10x1passive`, it is much easier for us to determine the function of each of the filter at a later time, without complicated inspection of the modelspec.

11.3 More Complex Initializers

What if you know the overall structure of the model we want to fit, but not the shape of the data coming in, and you want to adjust the model’s keywords to the data?

Most of the time, you can just adapt the first keyword. For example, “wc14x1” might become “wc18x1”, meaning the input data is expected to be a 14-channel spectrogram or an 18-channel spectrogram.

For more unusual initializations, you may need to write your own initializer function. This function can then study the data’s shape or values, it may accept arguments you need to define the “rough shape” of the model, and finally generates a modelspec.

It is perfectly acceptable (and recommended!) for one initializer to call another initializer. For example, in this case, we might call `nems.initializers.from_keywords()` after looking at the incoming data’s dimensionality and then deciding what keywords to use. In another case, we might look at the behavioral data and decide if we needed to use keywords corresponding to “active/passive” conditions or “reference/probe” conditions. Initializers may be specific to certain experimental types, for example.

Recommendation: Please try to preserve the 1-to-1 mappings created by the module keywords shorthands. One way to do this is to make your custom initializer also use the defaults keywords registry. This preserves our ability to search quickly through modelspecs to find ones containing keyword ids or parameters of interest, while also having the convenience of quickly generating models of a certain type.

11.4 Who decides what the keywords mean?

The default keyword registry is defined in `nems/keywords.py`. It is the place for “stable” keywords that are unlikely to be changed further.

During development, we recommend making your own personal keywords registry, and combining it with the defaults registry when creating modelspecs. Later, once your keywords are more stable, they may be migrated into the default registry.

For example,

```
import defaults import nems0.keywords.api

my_registry = {'mork1': {'fn': 'nems.modules.mork.spork',
                        'api': 'weight_channels',
                        'fn_kwargs': {},
                        'prior': [],
                        'phi': {}},

merged_registry = defaults.append(my_registry)

my_modelspec = initializers.from_keywords('wc18x1_mork1_dexp1',
                                           registry=merged_registry)
```

11.5 How do you save or load a modelspec?

`nems/modelspec.py` contains useful functions for loading and saving modelspecs in files. The four functions of interest are:

```
save_modelspec()    # Saves a single modelspec to a single file
save_modelspecls() # Saves a list of related modelspecls to multiple files
load_modelspec()   # Load a single modelspec from a single file.
load_modelspecls() # Loads multiple (related) modelspecls from multiple files
```

These simple functions are mostly to encourage uniform pattern for model and file names. You may override the default file name if desired, but for compatibility, the NEMS defaults for a model are generated using:

1. The keyword string that define the modelspec
4. The fitter used to find the parameters
2. The shorthand name of Recording object used to fit model parameters
3. The date and time, in ISO8601 format (Suggestion: 2018-02-02T19:02Z)

11.6 Allowed But Not Always Recommended: Prefitters

Because initializers are just functions, there is no limit to the operations you may perform when generating a modelspec. If necessary, you might write a `nems.initializers.fir_prefit` initializing function for this purpose to loosely prefilt the filter parameters (or even priors) to your data set. Because the initializer need not be saved with the modelspec, it need not be run again, and so loading the model at a later time will not have any increased performance penalties.

However, as an alternative to “baking in” this computation implicitly into a single initializer or keyword, we would instead recommend putting effort towards creating iterative or multi-stage fitting algorithms that work for all or most models. Fitters are more easily shared between a wide variety of models than initializers that usually are connected with specific keywords.

11.7 Future Work: Preprocessors in the Model

Our current strategy for performing preprocessing will be to use parameter-free modules and then to cache the results using memoization of those modules (probably via joblib).

TODO.

11.8 Under Debate: What additions to the modelspec have not yet been decided?

Items in discussion:

0. What should the keyword convention be? Last number is # of channels? Should there be any?
1. Should keywords be called “nicknames” instead? Or does nobody care?
2. Should keywords be generated from many small individual files so that we can track changes in git? Or is this ‘defaults’ and ‘private’ dictionary approach sufficient for now?
3. What should the “default” filename for models be?

4. Where should the “fitter” metadata be appended? Are the metedata properties of a modelspec the superset of all of the modules?

11.9 Priors

Priors: I pushed support for initializing phi from priors to the dev branch today. There are three functions that return modified (copies) of modelspecs with the phi initialized from the priors.

```
new_models = nems.priors.set_mean_phi(modelspec)
# or
new_models = nems.priors.set_random_phi(modelspec)
# or
new_models = nems.priors.set_percentile_phi(modelspec, 0.1)
```

A value of phi initialized using the idea of specific and general preferences:

1. Prefer a phi parameter already set in the module;
2. Otherwise, generate any uninitialized phi parameters from the prior of that module, if one exists;
3. Otherwise, fall back on priors defined the default_priors data structure to make any remaining uninitialized phi parameters.

You may mix and match. If you look at keywords.py below, you can see that I manually set the initial value of ‘amplitude’, manually define a prior for base, and let the the ‘shift’ and ‘kappa’ values be set by default.

```
defaults = {
    'wc40x1': {
        'fn': 'nems.modules.weight_channels.weight_channels',
        'fn_kwargs': {
            'i': 'stim',
            'o': 'pred'
        },
        'phi': {
            'coefficients': [
                [1.0, 1.0, 1.0, 1.0, 1.0, 1.0,
                 1.0, 1.0, 1.0, 1.0, 1.0, 1.0,
                 1.0, 1.0, 1.0, 1.0, 1.0, 1.0,
                 1.0, 1.0, 1.0, 1.0, 1.0, 1.0,
                 1.0, 1.0, 1.0, 1.0, 1.0, 1.0,
                 1.0, 1.0, 1.0, 1.0, 1.0, 1.0,
                 1.0, 1.0, 1.0, 1.0, 1.0, 1.0]
            ]
        }
    },
    'fir10x1': {
        'fn': 'nems.modules.fir.fir_filter',
        'fn_kwargs': {
            'i': 'pred',
            'o': 'pred'
        },
        'phi': {
            'coefficients': [
                [0.0, 1.0, 0.0, 0.0, 0.0, 0.0,
                 0.0, 0.0, 0.0, 0.0, 0.0, 0.0,
                 0.0, 0.0, 0.0, 0.0, 0.0, 0.0,
                 0.0, 0.0, 0.0, 0.0, 0.0, 0.0,
                 0.0, 0.0, 0.0, 0.0, 0.0, 0.0,
                 0.0, 0.0, 0.0, 0.0, 0.0, 0.0]
            ]
        }
    }
}
```

(continues on next page)

(continued from previous page)

```

        0.0, 0.0, 0.0, 0.0, 0.0]
    ]
},
'dexp1': {
    'fn': 'nems.modules.nonlinearity.double_exponential',
    'fn_kwargs': {
        'i': 'pred',
        'o': 'pred'
    },
    'phi': {'amplitude': 2.0},
    'prior': {'base': ('Normal', [0, 10])}
}
}
}

```

11.10 If not specified in the modelspec, these priors will be used

```

default_priors = {
    'nems.modules.fir.fir_filter': {
        'coefficients': ('Normal', [
            [[0, 0, 1, 0, 0, 0, 0, 0, 0], [
                [1, 1, 1, 1, 1, 1, 1, 1, 1]
            ]]
        ])
    },
    'nems.modules.nonlinearity.double_exponential': {
        'base': ('Normal', [0, 1]),
        'amplitude': ('HalfNormal', [0.5, 0.5]),
        'shift': ('Normal', [0, 1]),
        'kappa': ('HalfNormal', [0.5, 0.5])
    }
}

```

Note that in general, the size of the priors determine the size of phi. The exception to this is `default_priors` which should always be 1D so that people can use those very vague values as starting places for custom initializations with initializers.

CHAPTER
TWELVE

MODULES

Module perform a single transformation in the *modelspec* functional cascade. They should contain only string and numerical values (not functions themselves) so that they can be converted to JSON format for saving.

Each module is described by a dictionary with several key/value pairs. Some are required:

Required

- **fn**: pathspec to function that performs the transformation (e.g., `nems.modules.fir.basic`) This function should accept a Recording object and return a dictionary of signals, typically only signals that were modified or created by `fn`. These signals will be merged into the recording and passed to the next module in the *modelspec* cascade.
- **fn_kwargs**: dictionary of fixed args passed to `fn`. Can be empty, but typically contains:
 - `i`: name of input signal
 - `o`: name of output signal
 - `s` name of state signal
- **phi**: dictionary of free parameters, concatenated with `fn_kwargs` and passed to `fn` for evaluation. These parameters are updated during fitting.

Optional

- `plot_fns`
- `plot_fn_idx`
- `priors`

The only *mandatory* field in each module dict is `fn`. All other fields are optional. Presently, we have reserved the following fields for specific uses:

Field	Type	Description
<code>id</code>	str	Name of the module keyword that created this dict.
<code>fn</code>	str	The pure transformation function.
<code>fn_kwargs</code>	dict	Non-fittable arguments that are passed to <code>fn</code> .
<code>meta</code>	dict	A dictionary of metadata, descriptions, benchmarks, etc
<code>phi</code>	dict	Like <code>fn</code> , but fittable. The “parameters” of the module.
<code>prior</code>	dict	Defines a prior distribution from which bounds or samples may be drawn by the fitter during optimization.

You may place whatever information at all you like in `meta` without consulting anyone – “description”, “date”, “notes”, or information on fitters and data files are all good types of things to put in the `meta` dict. However, in the interests of forcing helpful design discussions, if you wish to establish a convention for another top-level field for modules, please bring it up in the [NEMS Gitter channel](#)

12.1 Making your own module

TODO

FITTERS

To keep fitters as simple and re-useable as possible, they should only require `sigma` (some representation of a point in fit-space, like a vector) and `cost_fn` (some function for determining error based on sigma) as arguments. This keeps fitter functions from needing to know anything about the model architecture, and ensures easy compatibility with popular fitting packages like `scipy.optimize.minimize`. Any additional functionality related to fitting, such as only fitting certain subsets of data or using a different fitter for a specific module, should be handled by an analysis (for a generalizeable function) or a script (for a very specific problem) as appropriate.

13.1 Termination Conditions

The termination conditions fitters are usually pretty similar, so we placed some generic termination condition functions in `fitters/termination_conditions.py`. Most fitters will have similar conditions for when to stop the fitting process: when the elapsed time, step size, or error delta reaches some value.

Termination condition functions should take in a `step_info` dict and return a boolean. If more than one condition should be checked, fitters may combine more than one termination conditions using the appropriate `and` or `or` expressions and a lambda function.

For example, many fitters look like:

```
import termination_conditions as tc

def my_fitter(sigma, cost_fn):

    stepinfo, update_stepinfo = tc.create_stepinfo()
    stop_fit = lambda : (tc.error_non_decreasing(stepinfo, tolerance) or
                         tc.max_iterations_reached(stepinfo, 1000))

    while not stop_fit():
        better_sigma = ...      # Find a better sigma somehow
        sigma = better_sigma
        err = cost_fn(sigma=sigma)
        update_stepinfo(err=err, sigma=sigma)

    return sigma
```

13.1.1 Conventions for Termination Conditions

- 1) The name of the function should describe the event that will cause the fitting loop to stop, and return True to indicate a stop. For example, `error_non_decreasing` returns a value of True when, as the name implies, the error is no longer decreasing by an amount at least equal to the specified tolerance.

As a result, fitters should generally refer to the `step_condition` in terms of: `if termination_condition::`. Using the reverse naming and return values should be avoided.

- 2) The expected structure of `step_info` is made with `create_stepinfo()`. For example:

```
stepinfo = {'num': 1,           # Num of steps taken thus far
            'err': 03.93,       # The cost to minimize
            'err_delta': None, # Change in cost since last step
            'start_time': time.time()
          }
```

These are the four default keys, but you may add more if you want to have more exotic termination conditions.

CHAPTER
FOURTEEN

PRIORS

TODO

XFORMS

15.1 What is the problem we trying to solve with XFORMS? What are XFORMS?

Often times, after fitting many different modelspecs and spending thousands of computer hours fitting models, you may find yourself needing to reload some models and the exact data that was used to fit it, for example when generating new plots. There are several ways that you could try to perfectly recreate the environment the model was fit in, and we will focus on two: 1) you could save a snapshot of the script used to fit the model; or 2) you could saving the recordings themselves (which may have been split into estimation, validation, and other sub-recordings).

XFORMS are essentially option #1. An xform (short for “transformation”) is at its essence a python function that takes in a dictionary and spits out a dictionary. We call these dictionaries the “context”, and they are a way of keeping track of variables that would otherwise be contained in the script namespace. This trick is easier in some languages, such as Lisps and other homoiconic languages, but still is useful in Python and not too difficult.

Basically, instead of writing a lines in a script like this:

```
rec = Recording.load("http://potoroo/baphy/271/bbl086b-11-1")  
  
rec = preproc.add_average_sig(rec,  
                               signal_to_average='resp',  
                               new_signalname='resp',  
                               epoch_regex='^STIM_')
```

You instead write a line in a list of xforms in a structure like this:

```
xfspec = [['nems.xforms.load_recordings', {'recording_uri_list': recordings}],  
          ['nems.xforms.add_average_sig', {'signal_to_average': 'resp',  
                                         'new_signalname': 'resp',  
                                         'epoch_regex': '^STIM_'}],
```

Note that the above is trivially serialized to JSON for saving. In ‘nems.xforms’ package, you capture the implicit variable `rec` in the xforms functions:

```
def load_recordings(recording_uri_list, **context):  
    ...  
    Load one or more recordings into memory given a list of URIs.  
    ...  
    rec = Recording.load(recording_uri_list[0])  
    other_recordings = [Recording.load(uri) for uri in recording_uri_list[1:]]  
    if other_recordings:
```

(continues on next page)

(continued from previous page)

```
    rec.concatenate_recordings(other_recordings)
    return {'rec': rec}

def add_average_sig(rec, signal_to_average, new_signalname, epoch_regex,
                    **context):
    rec = preproc.add_average_sig(rec,
                                  signal_to_average=signal_to_average,
                                  new_signalname=new_signalname,
                                  epoch_regex=epoch_regex)
    return {'rec': rec}
```

It's purely convention, but we advise keeping `nems.xforms` function names short and not doing too much inside each transform.

CHAPTER
SIXTEEN

DESIGN DISCUSSIONS

The following are a list of design discussion points that were brought up in our Slack conversations and may help inform why the design ended up the way that they did. It is probably not useful to non-developers.

16.1 DB ACCESS

Direct mysql DB access from nems0 is forbidden; instead, assume you have the files on disk (they can be fetched via HTTP, jerbs, DAT, or whatever)

16.2 MODELSPECS

The more I think about it, the more I wonder if our real goal should just be to exorcise all state from a module, turning modules into “pure functions” (a.k.a. functions without side effects). Not that we shouldn’t use classes, but that we should keep focused on stateless functions when possible.

Managing modules can be complicated precisely because they contain mutable state. Given that state is usually easier when it is all in once place, maybe packing the entire model into a single data structure isn’t such a crazy idea.

The following shows a little demo of how that might look in general, and for three cases that are not supported by the current version of NEMS: 1. “Per-module fitters”, when each module uses a different sub-fitter and all modules are iterated through. 2. “Parameter fitting dropout”, when some parameters are randomly NOT considered for optimization during the fitting process 3. “Module dropout”, when the transformation of random modules are temporarily omitted during the fitting process

The latter two techniques have been used extensively in deep learning and allegedly make the fitting process more robust. And per-module fitters could be a cleaner way of putting all the fitting code in a single place rather than spreading it out and putting a little in each module, which then requires that other fitters remove manually whenever they do not want to do an “initial-fit”.

16.3 MODELSPECS AND PHI

Q: Why is Phi part of the modelspec? I have to clone the modelspec each time I want to run a different fit on the model!

A: I’m conceptually thinking about modelspecs as being something that defines the entire input-output “black box” model; yes, the parameters (phi) are a special case in many cases, but they still fall within the black box and can’t be logically separated from it without having to lug around the knowledge that this phi goes with that black box, and this other phi goes with that other black box. I’m willing to pay the very slight extra memory use because I think we can optimize it away in other ways.

16.4 KEYWORDS

Our previous implementations of “keywords” were functions that could do anything. Now they are discouraged, because they were doing too many things at once: A) Appending of a module to a model; B) Initializing module parameters, which is better done with a JSON that describes prior beliefs about the values; C) Fitting module parameters. Our new strategy should be to use keywords as abbreviations that help create a modelspec.

16.5 MODULES MAY NOT INTROSPECT THE STACK

Modules are now forbidden from knowing anything about the rest of the stack. If you can think of a good reason why they absolutely need to see the rest of the stack, bring it up ASAP; otherwise we are going to plan to disallow this. Yes, this implies that STRF plots (which need multiple models) should be done by a function that takes in a model as an argument, not by a module method.

16.6 SIGNAL DIMENSIONS

I’d like to propose a simplification. In my opinion, the simplest and most general case for all data is for Signal objects to always be 2D: channel x time_sample, like a CSV file with each row being a moment in time. Trial-by-trial groupings shouldn’t matter for the evaluation of a module (I hope?), and not supporting 4D arrays gets rid of nasty problems that occur at the boundaries of a convolved signal when it is folded by trial. Basically, then, if you want to have a model that uses the data from 100 neurons, you can either have a 100 channel Signal, or 100 one-channel signals. It’s up to you.

16.7 SPLITTING DATA

I don’t think data splitting should be part of the Fitter class – data selection is a judgement call by the programmer before the fitting begins. You may want to use 3 data files as estimation data, and then use one for validation data. Or, you may want to use 60% of a single file as estimation data, and then 40% as validation. It really varies, and depends on the analysis. Also, some fitters accidentally have used the entire data set, not just the estimation data set; we should try to avoid this class of problems by keeping splitting out of the fitter.

16.8 FITTERS

This is the hardest part in my experience and needs the most thought. Just to muddy the waters a bit, here are some things that came up in the past: - People inadvertently cheating by using the whole data set for fitting, instead of just the estimation data set. - Fitting roughly at first with one algorithm, then fitting with another to get a final fit (it’s stupid, but it works better) - Iterating over all modules, fitting only parameters from one module at a time (it’s stupid, but it works often) - Fitting subsets of the parameters (to avoid n^2 performance penalties with some fitters) - Plugging in different cost functions for the same fitter (L1 vs L2 vs Log Likelihood) - Using one cost function for fitting, but multiple cost functions (metrics) for evaluating the final performance - Trying different termination conditions. Usually a predicate function that returns true when you should stop fitting. Reasons to stop fitting include a certain number of model evaluations, gradient step size, average change in error, too many NaN predictions, or elapsed time. - A helpful performance optimization in NARF was to avoid recomputing the entire stack; only recompute modules whose parameters were changed or had previous modules with changed parameters.

16.9 PRIORS AS SETTING BOUNDS

Every Module implements a get_priors method that takes one argument (the data being fit). The module may use this data to help come up with reasonable information about the fit bounds. For each parameter, a distribution is returned. This distribution defines the min/max and range of possible values. - So, for a value that can take on any positive values, you'd use a Gamma distribution. The mean of the gamma distribution ($E[x] = \alpha/\beta$) will be set to what you think is a reasonable value for that parameter. The fitter can then choose to set the initial value for the parameter to $E[x]$ or draw a random sample from the distribution. - For a value that can take on any value, you'd use a Normal centered at what a reasonable expected starting point for the value is. - For a value that must fall between 0 and 1 you can choose either a Uniform or Beta distribution. - For parameters that are multi-dimensional (e.g. FIR coefficients and mu in weight channels), the Priors can be multidimensional as well. So, for weight channels you can specify that the first channel is a Beta distribution such that the channel most likely falls at the lower end of the frequency axis and the second channel at the upper end of the frequency axis.

16.10 SUM_CHANNELS

Should this be renamed “sum_channels.py”? We might have a ‘sum_signals.py’ module at some point. Also: should this summing implementation be put in the “signals” object, which we then call from this file, in order that we don’t accidentally have two similar-but-not-identical versions of the same code? (I guess the answer to this depends on whether signals are passed between modules or not, as the same problem comes up with a “normalization” module and the Signal.normalize() methods)

16.11 Fitter Input Argument Specs

I think I may be arguing with my past self here, but I am wondering if we can remove the need to pass the “model” object to our fitting algorithms? I would ideally just prefer to have fitters accept a cost function, instead of having any knowledge about the model structure. I feel like any optimizations (evaluating part of the stack, per-module fitters) could still be accomplished with carefully structured functional composition.

16.12 Inter-module Data Exchange Format

Now that we have Signal objects, have we decided the data type once and for all? Numpy arrays? Or Signal/Recording objects? The former is probably more efficient, the latter is (debatably) more convenient for interoperability. Since the signal object was not available before, I can see that Brad assumed numpy arrays would be exchanged – is that necessary for Theano to work?

16.13 Lazy Devil’s Advocate

Q: To rethink a design decision, is it really worth wrapping all of the `scipy.stats` distributions with `nems.distributions`? instead of instead of using them directly? What specific advantages do we get from this?

A: It’s easier for us to control the behavior if we wrap the distributions. For example, look at `nems.distributions.Distribution.sample`. It’s not just a simple mapping to the underlying `scipy.stats` distribution.

16.14 SCIPY

I have functional versions of the modules, fitters and model portions of the system right now. To see how we can implement it using a bayes approach vs scipy, compare nems.fitters.scipy and nems.fitters.pymc3. The bayes approach is a very abstract system and requires quite a bit of knowledge re how PyMC3 (the bayes fitting package) works, so I haven't documented it in depth. Basically PyMC3 uses symbolic computation to build a symbolic model, then evaluates it once it's built.

16.15 ITERATIVE FITS

Stephen's very concerned about "mini-fits", so the iterative_fit function in the nems.fitters.scipy should hopefully alleviate his concerns.

16.16 FUNCTIONAL FITTERS

I've made the fitting routines functions (i.e., functional approach) rather than objects. It just seems to make more sense for these basic fits. There's no reason why some fitters can't be objects (e.g., if we are building a complex fitter with sub-fitters for each module and we need a central object to track the state).

16.17 ON THE NAMES OF FUNCTIONS

To help with clarity, we will define the following words mathematically:

Name	Function Signature and Description
EVALUATOR	f(mspec, data) -> pred Makes a prediction based on the model and data.
METRIC	f(pred) -> error Evaluates the accuracy of the prediction.
FITTER	f(mspec, cost_fn) -> mspec Tests various points and finds a better modelspec.
COST_FN	f(mspec) -> error A function that gives the cost (error) of each mspec. Often uses curried EST dataset, METRIC() and EVALUATOR()

where:

data	is a dict of signals, like {'stim': ..., 'resp': ..., ...}
pred	is a dict of signals, just like 'data' but containing 'pred'
mspec	is the modelspec data type, as was defined above
error	is a (scalar) measurement of the error between pred and resp

16.18 WHERE SHOULD THE DATASPEC BE RECORDED?

TODO: Open question: even though it is only a few lines, how and where should this information be recorded? The data set that a model was trained on is relevant information that should be serialized and recorded somewhere.

```
save_to_disk('/some/path/model1_dataspec.json',
            json.dumps({'URL': URL, 'est_val_split_frac': 0.8}))
```

TODO: This annotation should be done automatically when split_at_time is called?

16.19 Splitting, Jackknifing, and Epochs

@jacob In reply to your excellent question about what we should do for jackknifed_by_epochs and splitting based on epochs, and what data formats those should return, I think I made a mistake in asking for regex matching as part of the core functionality, and I'd like to walk that back a bit.

On the dev branch, I basically just removed the “regex” matching from split_at_epoch things, and things just worked fine. I didn’t fix jackknife_by_epochs yet, and I’m not entirely sure what the right way to do that is, and I’m open to ideas. My current hunch is to make it more like jackknife_by_time, and I’m guessing that rounding to the nearest occurrence of by_epochs would be the way to do it (and warn if the rounding is off results in partitions that, say, differ more than some critical amount). But I’m open to ideas.

Now, I still think regex functionality is cool, but after talking with SVD, I’m thinking we should do that in a single function, like `signal.match_epochs('regex')` which will give us a list of all matching epochnames that we can then iterate through.

Something like:

```
TORCs = signal.match_epochs('^TORC.*')

for torc in TORCs:
    my3dmatrix = signal.fold_by(torc)
    mean_for_this_torc = numpy.mean(my3dmatrix, axis=0)
    plot(mean_for_this_torc)
```

Mostly, I just wanted to avoid 4D arrays since they make my head hurt when they become ragged or partially NaN’d in strange ways.

I know we have gone over some of these points before, but I wanted to write down some of the things Stephen, Charlie, and I just discussed so that Jake and Brad have a chance to give their input as well.

We focused on Charlie’s analysis, which largely rests on analyzing the data and slicing it in unusual ways. It’s a good test case for the Signal/Recording stuff we have been working on. The data is >2000 seconds long, so sampled at 100Hz, the data matrix has more than 200,000 time samples.

START_TIME VS START_INDEX. We really need to get signals and epochs using absolute time and not bin indexes!

DATA EXCISION. One of the analyses is to find the average response to each stimulus. Some stimuli only occur 3 times, and are only 5.5 seconds long (550 samples). Right now, `fold_by('birdhonk.wav')` leaves you with a matrix that is 3 x C x T, where T is very large. We really need an argument to `fold_by()` that makes it excise data, so that we can make the output matrix be 3 x C x 550.

MULTI_FOLD_BY. I’m not sure what to call this, so please suggest a better name. `fold_by()` returns a 3D matrix, but what we need in several cases is to produce a dictionary in which the keys are the names of stimuli and the values are 3D matrices produced by `fold_by()` with excision. Something as simple as:

```
def multi_fold_by(signal, list_of_epoch_names): d = {ep : signal.fold_by(epoch_name) for ep in list_of_epoch_names} return d
```

INVERSE MULTI_FOLD_BY OPERATION. Another operation that we need is the inverse of `multi_fold_by()`. That is, a way of building up a Signal object from a dict of 2D matrices ($C \times T$) and an epochs data structure. This has two applications: 1) Creating a rasterized stimuli from a `stim_dict` (`test_parmread.py`: Line 46) and some epochs for when to start the stimuli 2) After using `mega_fold_by()` and averaging away the first dimension, in order to create a signal that is the same size as the original response, but has the ‘average’ response to every signal of a particular kind.

SUBCLASS OF SIGNAL. One thing that would also clearly be useful is a subclass of Signals that internally represents the data as unrasterized spike times, to save space, and then rasterizes it on demand to produce the matrix you want. This also gives us a ‘canonical form’ of our data, since you can produce many rasters from a single spike-time list. We agreed that it’s simplest just to raster everything for now, because our modules work on rastered data, and then at some point in the future we subclass `Signal` and store data internally in a different way.

PREPROCESSING. We have also had discussions about “preprocessing” vs models. One crazy idea is to use a model with zero fittable parameters to do preprocessing, so that you can preprocess signals in an unambiguous way. Then you feed those preprocessed signals into another model and do your fitting on that second model like normal.

IMMUTABILITY OF EPOCHS. Right now, epochs are mutable because they are panda dataframes, but the rest of the Signal is immutable. In the future, if we want to test the equality of two signals, this is easiest if they are completely immutable because we can just test the references instead of testing every substructure of the data.

OCCURRENCES vs REPETITIONS. A thought as we standardize our terminology and home in on best practice for signals and epochs. I suggest we use the word “occurrences” rather than “repetitions” when the number of times an epoch appears in a signal. To me, “repetitions” implies that each one is repeated/identical. This is fine for stimuli, but not true for responses. On the other hand, “occurrences” is not specific as to whether the occurrences are identical or not. Does that sound good?

Re: a comment in `demo_script.py` # TODO: temporary hack to avoid errors resulting from epochs not being defined. #for signal in rec.signals.values(): # signal.epochs = signal. trial_epochs_from_reps(nreps=10) # If there isn't a 'pred' signal yet, copy over 'stim' as the starting point. # TODO: still getting a key error for 'pred' in fit_basic when # calling lambda on metric. Not sure why, since it's explicitly added. I'm going to remove these; the former doesn't appear to be causing errors anymore, and the latter I think should be handled with explicit keywords. (see `modelspecs.md`, I just wrote it today) (edited)

TODO: @Ivar – per `architecture.svg` looked like this was going to be handled inside an analysis by a segmentor? Designed `fit_basic` with that in mind, so maybe this doesn’t go here anymore, or I may have had the wrong interpretation.
–jacob

TODO: @Ivar – Raised question in `fit_basic` of whether fitter should be exposed as argument to the analysis. Looks like that may have been your original intention here? But I think if the fitter is exposed, then the `FitSpaceMapper` also needs to be exposed since the type of mapping needed may change depending on which fitter is used.

These are both great questions that I am only just now getting to. I think yes, we handle the segmentation inside the analysis, and that as drawn in `architecture.svg`, we just have “data” and “modelspec” as the only two /required/ arguments to an analysis. However, it also totally makes sense to have /optional/ arguments for the segmentor, mapper, cost function, and anything else we come up with.

TODO: @Ivar – per `architecture.svg` looked like this was going to be handled inside an analysis by a segmentor? Designed `fit_basic` with that in mind, so maybe this doesn’t go here anymore, or I may have had the wrong interpretation.
–jacob

Yes, we will probably make two analyses at some point:

1. The outer analysis, which segments the data into a est and val dataset
2. The inner analysis, which may or may not segment the est dataset during the fitting process.

16.20 But for the moment, we'll leave the outer loop in demo_script.py.

Ideas on initializers:

Initializers are like: `f(data, incomplete_modelspec) -> modelspec_with_priors`. Or maybe `f(data, parameters) -> modelspec_with_priors`, where the parameters could be either ‘vague’ keywords or whatever needed?

The goal is that after initialization, when fitting is ready to start, we have a `modelspec` containing priors and keywords that help us find this model later.

There will be many kinds of initializers: if you have a particularly weird model, you may want to profit it in some weird way. If you want to start from another model, you might use the “start near this existing fit model” initializer. I leave it up to everybody to make their own initializers for specifically hard problems. Otherwise keywords may “just work” for simpler things.

**CHAPTER
SEVENTEEN**

HISTORY

NEMS is the third incarnation of a predictive modeling tool developed at the David Lab at Oregon Health & Science University, Portland, Oregon. The first incarnation, written in MATLAB, was called [NARF: the Neural Analysis Regression Framework](#), and was used to test about a million different models on neural data. The second version was a fairly literal port of NARF into Python, which was subsequently refactored into this current third incarnation to be more widely useable.

CHAPTER
EIGHTEEN

NGINX

NGINX (pronounced “engine-X”) is a very fast webserver for serving out static files, or for caching calls to a slower API.

18.1 Why use it?

18.1.1 File Transfer

Problem: You have a remote server from which you are repeatedly downloading the same files, over and over again, and it is obviously not only wasteful but slow.

Solution: Use a NGINX web server to cache some or all of the files locally so that when you browse to localhost, you get an identical copy of the remote file.

18.1.2 Slow API

Problem: A slow API is being called with the same arguments by many different computers, and the exact same value is being recomputed over and over again.

Solution: Use a NGINX web server as a proxy in front of the real API, and let NGINX handle all of the caching.

18.2 Installation

The first thing to do is turn off any other web servers that are running. In my case, apache2 happened to be installed and running, so I turned that off.

```
sudo service apache2 stop
```

Installing NGINX is straightforward on Ubuntu/Debian:

```
sudo apt-get install nginx
sudo service nginx start
```

In the `/etc/nginx/nginx.conf` file, I put the following in the `http` block. You may want to edit the path `/home/ivar/nginx/cache` to be another directory; that is just where I was testing. To make the cache hold data for 1 week, use this inside the `http` block:

```
# 10,080 minutes is 1 week
proxy_cache_path /home/ivar/nginx_cache levels=1:2 keys_zone=my_cache:10080m max_size=10g
    inactive=10080m use_temp_path=off;

server {
    location ~* {
        # access_log off;
        proxy_cache_valid any 10080m;
        proxy_cache my_cache;
        proxy_pass http://potoroo:3003;
    }
}
```

Finally, force the running server to reload the configuration:

```
sudo service nginx restart
```

You can now navigate to <http://localhost/> and observe that it hosts a cached copy.

You can watch the nginx access log in real time using:

```
sudo tail -f /var/log/nginx/access.log
```

18.3 Speed Test

Let's see how this improves the speed. The first call takes about 12 seconds:

```
time wget http://localhost/baphy/271/bbl086b-11-1
```

But the second time you run it, it takes about 52 milliseconds.

```
time wget http://localhost/baphy/271/bbl086b-11-1
```

18.4 How do I clear the cache?

When you want to clear the cache, simply delete the contents of the nginx_cache directory.
